TITLE: Germanium Phototriode

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy - Priborostroyeniye, 1958, Nr 5, pp 11-13 (USSR)

ABSTRACT: The article gives preliminary results of tests on flat germanium phototriodes. They are examined for their sensitivity. Qualities of voltage and amperage under varying lighting are also taken into consideration. Zh.I. Alferov, B.M. Konovalenko, S.M. Ryvkin, V.M. Tuchkevich, and A.I. Uvarov have done extensive studies in the field of flat hermanium phototriodes. Figure 1 shows the lighting layout of the germanium phototriode. Figure 3 shows statical volt-ampere characteristics of the phototriode under varying lighting. (1 - no light; 2 - lighting of 25 lux; 3 - lighting of 44 lux; 4 - lighting of 57 lux; 5 - lighting of 80 lux, and 6 - lighting of 124 lux). Figure

TITLE: Investigation of the Retardation of Electrons of Be and Ge by the Method of Secondary Emission (Issledovaniye tormozheniya elektronov v Be i Ge metodom vtorichnoy emissii)

PERIODICAL: Izv. vyssh. uchebn. zavedeniy. Fizika, 1958, Nr 1, pp 113-119

ABSTRACT: Results are adduced of an investigation of the secondary emission (SE) of thin films of Be, applied in a vacuum on a Ni base (I) and of thin films of Ge applied on Be (II). The coefficient of SE was determined for energies of primary electrons (PE) E_n ranging from 100 to 4000 ev. It was discovered that for I the $\sigma = f(E_n)$ curves have a minimum, the appearance of which can be explained by a large portion of the fast electrons emitted by the base when it is reached by the PE beam. From the relationships $\sigma = f(E_n)$ for I and $\sigma = f(\theta)$ (θ being the thickness of the Be layer) at various energies of the PE beam for II, the laws governing the retardation of electrons with energies from 1 to 3.5 ev were obtained. It is established that the law for the retardation for I and II has the form of $d \sim E^{1.4}$. R.O.

TITLE: The dependence of the long-wave limit of the photo-effect in p-n junctions of GaAs on the electric field

PERIODICAL: Fizika tverdogo tela, v. 4, no. 5, 1962, 1360 - 1363

TEXT: The variation of the photocurrent from GaAs crystals under the action of a strong electric field was investigated. The long-wave edge of the spectral characteristic was determined for a GaAs photo-diode with p-n junction. Results: (1) In the photon-energy range of 1.39 - 1.415 eV, the spectral characteristic is parallel to the curve for the absorption coefficient $k = f(\hbar\omega)$ (cf. T. S. Moss. J. Appl. Phys., 36, 2136, 1961) in the absence of an electric field. (2) When $\hbar\omega$ is less than 1.39 eV, the spectral characteristics for various voltages in the back direction begin to diverge. Hence, k becomes a function of the field strength. It was found that $I_{ph} = \int_{-w/2}^{+w/2} k dx$ when $k \ll 1/w$. Here, I_{ph} is the

Card 1/2

B101/B108

The dependence of the...

photo-current, W is the width of the space-charge region (= crystal), x is the coordinate counted from the center of the space charge. (3) The probability $\alpha(\omega)$ of quantum absorption was calculated from

$\alpha(\omega) = [A^2/m_{||}(\epsilon_0 - \hbar\omega)^{5/2}] \exp[-(4\sqrt{2m_{||}}/3\pi\hbar E)(\epsilon_0 - \hbar\omega)^{3/2}]$, where E is the field strength, A is a constant, $m_{||}$ is the reduced mass of the carrier pairs, and ϵ_0 is the forbidden band width. Assuming $m_n = 0.07 m_0$, $m_p = 0.6 m_0$, and $\epsilon_0 = 1.38$ eV qualitative agreement with experimental data was obtained. (4) If $\hbar\omega \sim \epsilon_0$, carriers excited by light in regions where $E = 0$ make large contributions to the photo-current. There are 2 figures.

TOPIC TAGS: gallium arsenide light generator, light-generating diode, gallium arsenide diode, carrier injection luminescence, injection luminescence, gallium arsenide laser, laser, carrier, luminescence, injection

ABSTRACT: A light-generating diode made of single crystal n-type gallium arsenide diffused with p-type zinc has been constructed and tested. Light emission was produced at room temperature by applying a pulsed current with pulse duration of 1-10 μ sec across the p-n junction. The obtained light spectrum showed two maxima centered at 0.95 and 1.3 μ . The time constant was less than 5×10^{-8} sec. At a maximum injection current of 20 amp the efficiency of the generator was about 0.1%. The authors hope to increase the photon flux several times by constructional refinements and the use of higher quality material. The author acknowledges that while the present article was being prepared for printing, the journal

NONLINEAR PHOTOEFFECT OF GaAs p-n JUNCTIONS (USSR)

Gutkin, A. A., D. N. Nasledov, and V. Ye. Sedov. Fizika tverdogo tela,
v. 5, no. 4, Apr 1963, 1138-1142. S/181/63/005/004/027/047

Two types of GaAs photodiodes were studied. The specimens were obtained by diffusion of acceptor-type dopants into n-type material with a carrier concentration of $\sim 10^{17} \text{ cm}^{-3}$ and a carrier mobility of $\sim 3200 \text{ cm}^2/\text{v}\cdot\text{sec}$. The p-region of the first type of sample was $\sim 10 \mu$ thick after diffusion and was decreased by etching in a boiling mixture (5NaOH (5%) + 1 H₂O₂ (30%) + 24H₂O) to $\sim 1 \mu$. The p-region of the second type was 1μ thick after diffusion and the specimens were not etched. Diffusion conditions were designed to produce a dopant-atom concentration of $\sim 10^{18} \text{ cm}^{-3}$ at the surface of the samples. Photocurrent characteristics, dependence of photosensitivity on bias light intensity, spectral distribution of photosensitivity with constant-spectrum bias light, dependence of photosensitivity on bias light wavelength, and spectral distribution of photosensitivity with a constant electric field applied to the illuminated p-surface were obtained. Specimens of the first type

Card 1/2

-AID Nr. 975-15 23 May

NONLINEAR PHOTOEFFECT [Cont'd]

S/181/63/005/004/027/047

had nonlinear photocurrent characteristics and exhibited increased photosensitivity with an increase in bias-light intensity. The nonlinear properties of the first type of diode are attributed to light-induced changes in the recombination rate at the illuminated p-surface. Specimens of the second type had linear photocurrent characteristics, and exhibited no dependence of photosensitivity on bias light. [BB]

TITLE: Spectral characteristics of gallium arsenide photoelements

SOURCE: Fizika tverdogo tela, v. 7, no. 1, 1965, 81-87

TOPIC TAGS: gallium arsenide, photoelectric effect, photoelectricity, photoelement, spectral characteristic, spectroscopy

ABSTRACT: Measurements of the spectral distribution of the effective quantum yield of GaAs photoelements have been made at temperatures of 78—430K and the results compared with Subashiyev's data (V. K. Subashiyev. FTT, 3, 3571, 1961). The measurements, carried out in the photon energy region of 1.3—3 ev, showed a strong effect of surface recombination on the photosensitivity of the samples; they showed also that the contribution of carriers generated by light in areas other than the p-n junction cannot be neglected in evaluating the photocurrent. The above findings apply principally to samples with highly alloyed surfaces not subjected to etching, the characteristics of which do not conform with those derived theoretically. It was also

Card 1/2

L 23950-65

ACCESSION NR: AP5003416

established that the spectral characteristics of gallium arsenide near the main absorption edge do not agree with the spectral distribution of the absorption coefficient of the starting material, which is due to the introduction of acceptor impurity in preparing the p-n junction. No recombination constants can be determined from the spectral characteristics in the region of the main absorption edge because of the optical nonhomogeneity there. Orig. art. has: 5 figures and 3 tables. (ZL)

TITLE: Effect of orientation of GaAs crystals on the depth and photoelectric properties of diffusion pn junctions

SOURCE: Fizika tverdogo tela, v. 7, no. 8, 1965, 2538-2539

TOPIC TAGS: gallium arsenide, pn junction, zinc, photoelectric cell, spectral distribution, photosensitivity

ABSTRACT: In view of some contradiction in earlier results (M. T. Minamoto and H. T. Malafi, J. Appl. Phys. v. 34, 1876, 1963) the authors have investigated the influence of orientation on the rate of diffusion of zinc by producing deep p-n junctions in plates having the same orientations as used in the preparation of photocells. The spectral distributions of the photosensitivity at photon energies 1.3--3 ev, of diffusion GaAs photocells which the authors produced under identical conditions, turned out to be practically the same, in spite of the fact that earlier results indicated that the position and form of the p-n junction should depend on the concentration and distribution of the dislocation. The initial material was single-crystal GaAs of n-type with electron density $(2-3) \times 10^{17} \text{ cm}^{-3}$ and mobility $3500-4000 \text{ cm}^2 \text{ v}^{-1} \text{ sec}^{-1}$ grown horizontally by the Bridgman method.

Card 1/2

0702004

L 6337-66

ACCESSION NR: AP5019882

The treatment of the crystals is described. The results show that the thickness of the p-layer, and consequently the diffusion coefficient of the zinc, does not depend on the orientation. Addition of arsenic into the ampoule greatly reduces the diffusion coefficient of zinc. This result agrees with that of L. J. Vieland (J. Phys. Chem. Sol. v. 21, 318, 1961). Orig. art. has: 1 table.

TITLE: Spectral characteristics of GaAs p-n junctions in the near-
ultraviolet

SOURCE: Fizika tverdogo tela, v. 8, no. 3, 1966, 712-716

TOPIC TAGS: gallium arsenide, p n junction, spectral energy distribution

ABSTRACT: The photosensitivity of GaAs p-n junctions was measured up to photon energies of 5.4 ev and at temperatures of 90, 293, and 370K. The investigations were made with the use of a quartz double monochromator during illumination of both the n- and p-surfaces of the samples. At photon energies higher than 3 ev, the photosensitivity increased slightly and then leveled off, only to increase again slightly at about 5 ev. The shapes of the characteristics remained similar during the illumination of the n- and p-surfaces. It is considered probable that the structure of the spectral characteristics of GaAs in the

Card 1/2

L 21185-66

TITLE: Photosensitivity spectra of p-n junctions in InAs in the photon energy range
0.9 - 5 eV

SOURCE: Fizika tverdogo tela, v. 8, no. 7, 1966, 2044-2047

TOPIC TAGS: pn junction, photosensitivity, internal photoeffect, indium compound
optic material, arsenide, spectral distribution, absorption coefficient, quantum yield

ABSTRACT: This is a continuation of earlier work (FTT v. 8, 712, 1966), where it was
observed that the spectral distribution of the quantum yield of the internal photoef-
fect in the short-range region is connected with singularities of the band structure
of GaAs. The present work extends the investigation to InAs. The InAs p-n junctions
were obtained by diffusion of Cd in n-type material with electron density $(0.5 - 1) \times 10^{17} \text{ cm}^{-3}$
and were produced at a depth of several microns. The hole concentration
in the illuminated surface of the sample was approximately 10^{18} cm^{-3} . Several p-n
junctions illuminated from the n-side were also tested. The long-wave part of the
spectral characteristic of the junction was plotted with the aid of a ZMR-2 mono-
chromator, and the measurements at higher energies were by the procedure described in
the earlier paper. The measurements showed a narrow long-wave photosensitivity peak,

Card 1/2

04791-67

ACC NR: AP6024462

2

connected with the change of the absorption coefficient near the edge of the ground-state band, followed by a region of weak variation, a faster growth at $\sim 0.7 - 1$ eV photon energy, a reversal followed by minimum near 3.2 eV, and a renewed growth at higher energies. The results are shown to be connected with the variation of the quantum yield of the internal photoeffect as a result of secondary ionization. The threshold energy of the photon, starting with which the quantum yield begins to grow, is found to be 0.7 - 0.8 eV at 293K and 0.9 - 1 eV at 100K, in agreement with theoretical calculations by others. The various sections of the spectrum are interpreted on this basis, and it is indicated in the conclusion that the actual quantum yield may not be as large as what follows from theoretical considerations, since account must be taken of the probability ratios of the different electronic transitions. The authors thank N. P. Yesina and N. N. Smirnova for preparing the InAs p-n junctions. Orig. art. has: 3 figures.

TITLE: Spectral characteristics of GaP--GaAs photocells in the photon energy region
up to 5.4 eV

SOURCE: Fizika tverdogo tela, v. 8, no. 10, 1966, 3097-3099

TOPIC TAGS: gallium arsenide, gallium phosphide, gallium optic material, pn
junction, photoelectric cell, photosensitivity

ABSTRACT: This is a continuation of earlier work (Kosmicheskiye issledovaniya, IV, 128, 1966 and preceding papers) where the possibilities of GaP--GaAs p-n junctions were first revealed and studied. The present paper describes investigations of the photosensitivity of junctions prepared by diffusion of zinc in a GaAs plate in which a region of variable composition $\text{GaP}_x\text{As}_{(1-x)}$ was produced beforehand by heating in phosphorus vapor. The preparation procedure and some properties of such a junction were described earlier. The illuminated surface was subjected to various degrees of

Card 1/2

L 08129-67

ACC NR: AP6033579

3

etching. The tests consisted of plotting the photocurrent spectra and the spectrum of the diffuse reflection from the surface. X-ray analysis of the junction structure, and the presence of a peak near 3.6 eV, reveal that the surface layer of the photocell contains not less than 90% of GaP and consequently its photosensitivity spectrum is governed by the band structure of GaP. Comparison of the reflection and photosensitivity spectra shows that the photocurrent per incident absorbed photon is constant (at $h\nu \sim 2.5-4.6$ eV) and then drops off slightly towards 5.4 eV. This is also confirms the GaP-type band structure, which precludes any possible increase of the quantum yield for photons with energy lower than ~ 5.2 eV, when the internal photoeffect and impact ionization come into play. The fact that the quantum yield remains constant over a wide range of photon energies extending over different parts of the Brillouin zone shows that the minority nonequilibrium carriers (electrons) excited by the photons in different parts of the conduction band have time to go over to the equilibrium state at room temperature within a time shorter than the carrier lifetime ($\leq 10^{-9}$ sec). Consequently the drop in photosensitivity in the 2.6--3.5 eV region, which decreases strongly when the cell surface is etched, may be due to an increased role of surface recombination with increasing absorption coefficient, and not to a decrease in lifetime. The authors thank A. S. Toporets, A. V. Sheklein, and N. B. Rekant for measuring the diffuse-reflection spectra. Orig. art. has: 1 figure.

TITLE: Spectral characteristics of GaP--GaAs photocells in the photon energy region
up to 5.4 ev

SOURCE: Fizika tverdogo tela, v. 8, no. 10, 1966, 3097-3099

TOPIC TAGS: gallium arsenide, gallium phosphide, gallium optic material, pn
junction, photoelectric cell, photosensitivity

ABSTRACT: This is a continuation of earlier work (Kosmicheskiye issledovaniya, IV, 128, 1966 and preceding papers) where the possibilities of GaP--GaAs p-n junctions were first revealed and studied. The present paper describes investigations of the photosensitivity of junctions prepared by diffusion of zinc in a GaAs plate in which a region of variable composition GaP_xAs_(1-x) was produced beforehand by heating in phosphorus vapor. The preparation procedure and some properties of such a junction were described earlier. The illuminated surface was subjected to various degrees of

3

etching. The tests consisted of plotting the photocurrent spectra and the spectrum of the diffuse reflection from the surface. X-ray analysis of the junction structure, and the presence of a peak near 3.6 eV, reveal that the surface layer of the photocell contains not less than 90% of GaP and consequently its photosensitivity spectrum is governed by the band structure of GaP. Comparison of the reflection and photosensitivity spectra shows that the photocurrent per incident absorbed photon is constant (at $h\nu \sim 2.5-4.6$ eV) and then drops off slightly towards 5.4 eV. This is also confirms the GaP-type band structure, which precludes any possible increase of the quantum yield for photons with energy lower than ~ 5.2 eV, when the internal photoeffect and impact ionization come into play. The fact that the quantum yield remains constant over a wide range of photon energies extending over different parts of the Brillouin zone shows that the minority nonequilibrium carriers (electrons) excited by the photons in different parts of the conduction band have time to go over to the equilibrium state at room temperature within a time shorter than the carrier lifetime ($\leq 10^{-9}$ sec). Consequently the drop in photosensitivity in the 2.6-3.5 eV region, which decreases strongly when the cell surface is etched, may be due to an increased role of surface recombination with increasing absorption coefficient, and not to a decrease in lifetime. The authors thank A. S. Toporets, A. V. Sheklein, and N. B. Rekant for measuring the diffuse-reflection spectra. Orig. art. has: 1 figure.

GUTKIN, A M

Gutkin, A. M. Concerning the theory of vapor. Akad. Nauk SSSR. Zhurnal Eksper. Teoret. Fiz. 20, 538-546 (1950). (Russian)

Pour étudier théoriquement les propriétés d'une vapeur saturée et surchauffée on considère fréquemment la vapeur comme un mélange d'un grand nombre de gaz. Le premier gaz du mélange est composé de molécules sans action les unes sur les autres; chaque particule du second gaz est formée d'une paire de molécules en interaction, mais sans action sur le reste des molécules, etc. La particule du même gaz est composée de n -molécules en interaction mais sans influence sur les autres. Pour chacun de ces gaz on calcule son énergie libre et l'énergie libre de la vapeur, ainsi que le nombre des molécules de chaque gaz, sont calculées par la condition de minimum d'énergie libre dans un mélange

gazeux. Frenkel [Kinetic Theory of Liquids, Oxford, 1946; ces Rev. 9, 168] considère chacun de ces gaz comme un gaz parfait. Bond [J. Chem. Phys. 7, 324-326, 927-931 (1939)] et Tseng, Feng, Cheng, et Band [ibid. 8, 20-25 (1940)] introduisent une correction en calculant le volume propre de la vapeur. L'auteur reprend le calcul du volume propre de la molécule de vapeur en deux approximations successives et montre que, pour certaines valeurs de la densité de la vapeur, les termes de la seconde approximation peuvent devenir comparables à ceux de la première approximation. Il étudie le rôle des chocs élastiques et non élastiques. Il donne deux méthodes pour calculer la somme des états de la vapeur, l'une analogue à celle d'Ursell et une autre à celle de Frenkel. Il montre finalement que certaines considérations de Band paraissent improbables. M. Kivelsonitch

Title : Some questions on the theory of plastic flow

Periodical : Izv. AN SSSR, Otd. Tekh. Nauk 9, 37-42, Sep 55

Abstract : The article was originally presented at the conference on the theory of elasticity, the theory of plasticity and theoretical structural mechanics held at the Institute of Mechanics Acad Sci USSR on 25 December 1954. Presents mathematical solution of two cases of plastic flow. Relates flow to linear, conical and spherical motion. Lists series of theoretical conclusions for cases studied. Formulae, diagram. Fifteen references, 10 USSR.

847. Gutkin, A. M., Motion of a viscous-plastic medium in a gap between two rotating cones (in Russian), *Kollekt. Zh.*, 17, 6, 421-423, 1955; Ref. Zh. Mekh. 1956, Rev. 3386.

Solution of the problem of motion of a viscous-plastic medium in a gap between two rotating co-axial cones having a common apex. By integration of the state equations of the viscous-plastic medium in spherical coordinates an expression was obtained for the case when the displacement covers the whole region between the cones:

$$\omega = \left(\frac{3M}{2\pi R^3 \mu} - \frac{2r_0}{\mu} \right) \int_{\alpha}^{\beta} \frac{d\theta}{\sin^3 \theta} + \frac{r_0}{\mu} \left(\frac{\cos \alpha}{\sin^2 \alpha} - \frac{\cos \beta}{\sin^2 \beta} \right)$$

where ω is the angular velocity of the rotating cone, M is the rotational moment, R is the portion of the gap filled according to the generatrix of the cone, r_0 is the limiting stress of the displacement, μ is the plastic viscosity, and 2α and 2β are the cone angles.

A similar equation was obtained for the case when the displacement does not cover the whole region between the cones, i.e., there is a zone of elastic deformation where the stress is less than r_0 .

In solving the problem it was assumed that the boundary of the viscous-plastic medium filling the space between the cones is a spherical surface.

TITLE:

The Use of the ¹⁹Alpha Radiation of Radioactive Isotopes in
Instruments for the Control of the Dimensions of Work-
pieces During Their Grinding

PERIODICAL: Atomnaya energiya, 1960, Vol. 8, No. 6, pp. 576-578

TEXT: The authors have developed a new method for the automatic control of the size of workpieces that are being ground. This method has a high degree of accuracy, and has been tested by the authors under laboratory and industrial conditions. It is based on the dependence of the number of particles reaching a counter upon the area of the cross section of the workpiece penetrated by them. Fig. 1 shows the circuit diagram of the primary element (radioizotopnyy datchik), which is then described. An end-window counter of the type MCT-17 (MST-17) is used. When the instrument is adjusted for a certain size of the piece to be ground, the grinding process is automatically interrupted as soon as this size is attained.

A thorium isotope is used as alpha source. A photograph of the whole instrument is shown in Fig. 3. It was first tested in a laboratory, and then introduced in the "Sibzavod" at Omsk. One command proved to be insufficient in many cases. The feeler shown in Fig. 3 can transmit three commands to the machine: 1) one command for the change from rough to fine machining as soon as the dimension of the workpiece exceeds the final size by 30 - 60 microns; 2) one command for stopping the fine machining as soon as the dimension exceeds the final dimension by 10 - 15 μ ; machining is continued when the feed of the grinding wheel has been switched off; 3) a signal for the quick removal of the grinding wheel as soon as the workpiece has attained its final size. The individual stages of this process are indicated by the lighting of three different lamps (1,2,3 in Fig. 3) on the instrument. Accordingly, the instrument has two dials (rough and fine) indicating the amount to be removed. The change from the "rough" to the "fine" dial also takes place automatically. There are 3 figures and 1 Soviet reference.

TITLE: Spiral Motion of a Cylinder in a Visco-plastic Disperse System
PERIODICAL: Kolloidnyy zhurnal, 1960, Vol. 22, No. 5, pp. 569-572

TEXT: The author has already reported on a theoretical investigation of the spiral flow of visco-plastic disperse systems (Ref. 1) at the 1-y Vsesoyuznyy s"yezd po mekhanike (First All-Union Conference on Mechanics) in 1960. Since this flow with double shearing is important for rheological measurements, the author discusses a flow of this kind assuming that the motion is caused by a long round cylinder of radius a , and that is the visco-plastic medium unlimited. It is further assumed that no gliding takes place between the cylinder surface and the medium in which it is immersed. Proceeding from the Henki-Il'yushin equation (Ref. 2), the velocity distribution in the visco-plastic medium, caused by the spiral motion of the cylinder, is determined. The relationship between torque axial force (acting upon the cylinder), and velocity components of the spiral motion of the cylinder is determined. A method is suggested for the

TITLE: The Flow of a Visco-plastic Disperse System on a Rotating Disk

PERIODICAL: Kolloidnyy zhurnal, 1960, Vol. 22, No. 5, pp. 573-575

TEXT: The most simple method of studying the behavior of visco-plastic consistent lubricants in rotating friction units is to examine the flow of a lubricant on a revolving disk. This problem has already been investigated (Ref. 1); since, however, wrong theoretical assumptions had been made the results were also incorrect. In the present paper, first the case is investigated where a thin layer h of the lubricant is applied to the disk which is caused to rotate so quickly that the thickness of the lubricant layer does not change before a certain speed ω has been reached. In the following it is shown that the limiting shearing stress τ_0 of the lubricant can be expressed by the following equation:

$$\tau_0 = \rho \omega^2 (1 - z_0) \quad (7) \quad (\rho = \text{density of the lubricant, } \omega = \text{angular velocity, } \checkmark)$$

Card 1/2

84275

The Flow of a Visco-plastic Disperse System on a Rotating Disk S/069/60/022/005/005/011
B015/B064

r = radius of the cylinder) wherefrom the value for z_c may be calculated. This leads the equation for the amount of lubricant passing through the cylinder surface of radius r :

$$Q = \frac{\pi \rho \omega^2 r^2}{3\mu} \left(1 - \frac{\tau_0^2}{\rho \omega^2 r}\right) \left(5l - \frac{\tau_0}{\rho \omega^2 r}\right) \quad (13).$$

In the second approximation, the following relation can be written down: $l = h - \frac{h^2}{3\mu} \left(5\rho \omega^2 h - \frac{11}{2} \frac{\tau_0}{r}\right) + \frac{25\rho^2 \omega^4 h^5}{6\mu^2}$ (17), where μ = plastic viscosity of the lubricant, t = time,

and l = thickness of the lubricant layer. If equation (17) is introduced into (13) instead of l , the lubricant consumption can be determined as a function of time if the values of t are not too high. There are 2 Soviet references.

TITLE: The Flow of a Viscoplastic Medium Between Rotating Disks

PERIODICAL: Doklady Akademii nauk SSSR, 1960, Vol. 134, No. 5,
pp. 1048 - 1050

TEXT: The parallel rotating disks are supposed to be rigid and coarse, and the distance between the two disks to be smaller than their linear dimensions. Since the medium between the disks is relatively low, the following relations can be written in first approximation after equilibrium is established: $-\partial p / \partial r + \partial \tau_{rz} / \partial z + q \omega^2 r = 0$ (6) $\partial p / \partial z = 0$ (7). From these relations, the equation $\tau_{rz} = (dp/dr - q \omega^2 r)z + C$ (8) is obtained for the shearing stress, and thence, in turn, $v_r = \frac{\tau}{\mu}(z-h) + \frac{1}{2\mu}(dp/dr - q \omega^2 r)(z^2 - h^2)$ (10). Next, the following relation is obtained for the output Q :

Card 1/3

84825

The Flow of a Viscoplastic Medium Between
Rotating Disks

S/020/60/134/005/008/023
B019/B060

$$Q = 4\pi r v_0 z_0 + 4\pi r \int_{z_0}^h v_r dz = \frac{4\pi r}{3\mu} \left[(q\omega^2 r - dp/dr)(h^3 - z_0^3) + \frac{3}{2}\tau_0(z_0^2 - h^2) \right].$$

Finally, two special cases are examined. In the first one, two massive disks are considered to be approaching at the small velocity U , while in the second case, a viscoplastic medium is supposed to be steadily added

between the disks. The differential equation $dp/dr = q\omega^2 r - 3\tau_0/2h$
- $3\mu Q/4\pi rh^3$ (20), and, by integration $p_1 - p_2 = \frac{q\omega^2}{2}(a^2 - R^2) + \frac{3\mu Q}{4\pi h^3} \ln \frac{R}{a}$

+ $\frac{3\tau_0}{2h}(R - a)$ (21), are obtained. Here, p_1 is the pressure at $r = a$ (a being the aperture diameter, through which there enters the viscoplastic medium), and p_2 is the pressure at $r = R$. N. V. Ryabin (Ref. 1) is mentioned. There is 1 Soviet reference.

TITLE: Extrusion of a viscoplastic medium between sliding plane-parallel walls

PERIODICAL: Kolloidnyy zhurnal, v. 23, no. 1, 1961, 20-24

TEXT: The problem of the flow of a viscoplastic Shvedov-Bingham medium in a plane capillary under the action of pressure, which acts in one direction, as well as of the tangential stress is dealt with, which acts in perpendicular direction. The axis is orientated perpendicular to the walls (Fig.). The flow per unit length of the capillary tube is

$$Q = 2(v_z x_1 + \int_{x_1}^a v_z dx) = -(2/3\mu)(dp/dz)(a^3 - x_1^3) - (\theta/\mu) a \sqrt{a^2 + x_1^2} / (dp/dz)^2$$

$$- x_1 \theta / (dp/dz) + \theta r^2 / \mu (dp/dz)^2 \ln [a (dp/dz)]$$

Card 1/6

20017

S/069/61/023/001/002/009
B020/B056

Extrusion of a viscoplastic ...

$+ \sqrt{\tau^2 + a^2 (|dp/dz|)^2} / (\theta + \sqrt{\theta^2 - \tau^2})$ (15), (where τ denotes tangential stress, θ - the limiting tensile stress), which is correct only when $\tau \leq \theta$. When $\tau \geq \theta$, the width of the elastic zone vanishes and for the flow through the unit length of the capillary tube, relation (16) holds.

$$Q = -\frac{2a^3}{3\mu} \frac{dp}{dz} - \frac{\theta a}{\mu} \sqrt{a^2 + \frac{\tau^2}{\left(\frac{dp}{dz}\right)^2}} + \frac{\theta \tau^3}{\mu \left(\frac{dp}{dz}\right)^2} \ln \frac{a \left|\frac{dp}{dz}\right| + \sqrt{\tau^2 + a^2 \left(\frac{dp}{dz}\right)^2}}{\tau} \quad (16)$$

The velocity v_y is obtained from equation

$dv_y/dx = \tau/\mu - \theta/\mu \sqrt{1 + (x^2/\tau^2)(dp/dz)^2}$ (12), if it is assumed that the left layer of liquid of the capillary tube is immobile, i.e., $v_y = 0$; with $x = -a$

Card 2/6

Extrusion of a viscoplastic ...

$$v_y = \frac{\tau(x+a)}{\mu} - \frac{\theta\tau}{\mu \left| \frac{dp}{dz} \right|} \ln \frac{\left| \frac{dp}{dz} \right| x + \sqrt{\tau^2 + x^2 \left(\frac{dp}{dz} \right)^2}}{-\left| \frac{dp}{dz} \right| a + \sqrt{\tau^2 + a^2 \left(\frac{dp}{dz} \right)^2}} \quad (17)$$

and with $-a \leq x \leq -x_1$

$$v_y = \frac{\tau(a-2x_1+x)}{\mu} - \frac{\theta\tau}{\mu \left| \frac{dp}{dz} \right|} \ln \frac{\left(-x_1 \left| \frac{dp}{dz} \right| + \sqrt{\tau^2 + x_1^2 \left(\frac{dp}{dz} \right)^2} \right) \left(x \left| \frac{dp}{dz} \right| + \sqrt{\tau^2 + x^2 \left(\frac{dp}{dz} \right)^2} \right)}{\left(x_1 \left| \frac{dp}{dz} \right| + \sqrt{\tau^2 + x_1^2 \left(\frac{dp}{dz} \right)^2} \right) \left(-a \left| \frac{dp}{dz} \right| + \sqrt{\tau^2 + a^2 \left(\frac{dp}{dz} \right)^2} \right)} \quad (18)$$

The velocity of the right liquid layer for given quantities dp/dz and τ is given by

Card 3/6

20017

S/069/61/023/001/002/009
B020/B056

Extrusion of a viscoplastic ...

$$u_y = \frac{2\tau(a-x_1)}{\mu} - \frac{20\tau}{\mu \left| \frac{dp}{dz} \right|} \ln \frac{\left(a \left| \frac{dp}{dz} \right| + \sqrt{\tau^2 + a^2 \left(\frac{dp}{dz} \right)^2} \right) \left(-x_1 \left| \frac{dp}{dz} \right| + \sqrt{\tau^2 + x_1^2 \left(\frac{dp}{dz} \right)^2} \right)}{\tau^2} \quad (19)$$

In the absence of the elastic zone, i.e., if $\tau \geq 0$, with $x_1=0$, equation

$$u_y = \frac{2\tau a}{\mu} - \frac{20\tau}{\mu \left| \frac{dp}{dz} \right|} \ln \frac{a \left| \frac{dp}{dz} \right| + \sqrt{\tau^2 + a^2 \left(\frac{dp}{dz} \right)^2}}{\tau} \quad (20)$$

is obtained for the velocity of the right liquid layer from (19). From this it follows that for a viscoplastic disperse system, in contrast to a truly viscous liquid, both components of the flow velocity tensor depend upon the amount of both flow-affecting stresses. Finally, it is said that the equations obtained in the present paper hold also for the case of extrusion of a disperse system in a narrow clearance between two coaxial

Card 4/6

20017

S/069/61/023/001/002/009
B020/B056

Extrusion of a viscoplastic ...

cylinders, one of which rotates. An exception exists only if the tangential stress τ applied to any cylinder differs only little from the limiting tensile stress θ , and if also the pressure gradient is small, i.e., if the conditions

$$|\theta - \tau|/\theta \leq 1, \text{ and } |dp/dz|/\theta \leq 1.$$

are satisfied. In this case, the inequality of tensile stress on the surface of the inner and outer cylinder acquires decisive importance. Within the entire remaining region of tensile stresses, the flow θ through a narrow clearance between two cylinders of radii R_1 and R_2 and

height L may be calculated from (15) and (16). For this purpose, θ may be multiplied in the equations (15) and (16) by $\pi(R_1+R_2)$, and instead of

$$a = (R_2 - R_1/2) \quad (21), \text{ instead of } \tau = M/[\pi(R_1+R_2)L] \quad (22), \text{ and}$$

$$x_1 = (\sqrt{\theta^2 - \tau^2})/|dp/dz| \text{ at } \tau < \theta \quad (23) \text{ and } x_1 = 0 \text{ must be substituted at}$$

$\tau > \theta$. The angular velocity of the inner cylinder may be calculated from the equations (19) and (20), if v is divided by $R=1/2(R_1+R_2)$, and is substituted from equations (21)-(23). G. V. Vinogradov, V. P. Pavlov,

AUTHOR: Gutkin, A. M.

TITLE: Slow compression of a viscoplastic disperse system

PERIODICAL: Kolloidnyy zhurnal, v. 24, no. 1, 1962, 8 - 10

TEXT: The slow flow of a viscoplastic disperse system between two coarse, rigid, parallel plates in the form of a band or disc was studied. For the band-shaped system, the force F acting during compression of the plates per unit length of the band is:

$$F = 2bp_0 + \tau_0 b^2/a + (4/5)(\eta U \tau_0/a^4)^{1/2} + 4\eta U b^3/9a^3$$

($2a$ = thickness of the system; $2b$ = breadth), for the disc-shaped system:

$$F = \pi R^2 p_0 + \pi R^3 \tau_0/2a + (2\pi/7)(\eta U \tau_0 R^7/2a^4)^{1/2} + \pi \eta U R^4/12a^3$$

(R = radius). The relationship between the acting force and the velocity U at which the compressed plates are approaching is expressed by equation

Card 1/3.

Slow compression of a viscoplastic ...

S/069/62/024/001/001/003
B119/B101

$$U = \frac{25}{32} \frac{\left(F - 2bp_0 - \frac{\tau_0 b^2}{a}\right)^3 \tau_0 a^4}{\eta b^5} \left[1 - \frac{25a \left(F - 2bp_0 - \frac{\tau_0 b^2}{a}\right)}{18\tau_0 b^2} \right] \quad (9)$$

for the band-shaped, and by equation

$$U = \frac{49a^4 \left(F - \pi R^2 p_0 - \frac{\pi R^3 \tau_0}{2a}\right)^2}{2\pi^3 \eta \tau_0 R^2} \left[1 - \frac{49a \left(F - \pi R^2 p_0 - \frac{\pi R^3 \tau_0}{2a}\right)}{12R^2 \tau_0} \right] \quad (13)$$

for the disc-shaped system. The lateral pressure coefficient χ depends on the shape of the system and on the value of the lateral pressure.
 $\chi = p_0 / (p_0 + \tau_0 b / 2a)$ for the band-shaped system, and $\chi = p_0 / (p_0 + \tau_0 R / 2a)$ for the disc-shaped system. There are 1 figure and 2 Soviet references.
